(54) Abstract Title: Redundant telemetry system

(57) A drill string 6 comprises adapter subs 9, 9a, 9b within the string that are separated from each other by at least three lengths of drill pipe. The adapter subs 9, 9a, 9b are connected together by a communication cable 5a which may be as a wired drill pipe (WDP). In the event that the cable 5a should fail an alternative cable 5b can ensure that communication between adapter subs 9, 9a, 9b is maintained by acting as a by-pass. Cable 5b carries sub connectors 118 with inductive couplers 120 for communication with inductive couplers 114 within the adapter subs 9. The sub connectors 118 include a key or arm 124 which can engage in an annular recess 116 in the adapter sub 9 to locate the connector 118 correctly.

DOWNHOLE TELEMETRY SYSTEM AND METHOD

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to drill string telemetry. More specifically, the invention relates to wired drill pipe telemetry systems and techniques for transmitting signals through a drillstring.

2. Related Art

Downhole systems, such as Measurement While Drilling (MWD) and Logging While Drilling (LWD) systems, derive much of their value from their abilities to provide real-time information about borehole conditions and/or subsurface formation properties. These downhole measurements may be used to make decisions during the drilling process or to take advantage of sophisticated drilling techniques, such as geosteering. These techniques rely heavily on instantaneous knowledge of the wellbore and surrounding formation that is being drilled. Therefore, it is important to be able to send large amounts of data from the MWD/LWD tool to the surface and to send commands from the MWD/LWD tools to the surface with a minimum time delay. A number of telemetry techniques have been developed for such communications, including wired drill pipe (WDP) telemetry.

The concept of placing a conductive wire in a drill string has been around for some time. For example, U.S. Patent No. 4,126,848 issued to Denison discloses a drill string telemeter system, wherein a wireline is used to transmit the information from the bottom of the borehole to an intermediate position in the drill string, and a special drilling string, having an insulated electrical conductor and employing ring-shaped electrical contact connectors, as described in U.S. Patent No. 3,696,332 issued to Dickson, Jr. et al., is used to transmit the information from the intermediate position to the surface. Russian Federation Patent No. RU 2,140,537C1 to Basarygin et al. similarly discloses a hybrid telemetry drill string system having a lower wireline system serially connected to an upper WDP system.

U.S. Patent No. 3,957,118 issued to Barry et al. discloses a releasable cable and latch system for drill string telemetry in drill pipe joints that are not otherwise wired. U.S. Patent No. 3,807,502 issued to Heilhecker et al., and U.S. Patent Nos. 4,806,928 and 4,901,069 to Veneruso similarly disclose methods and apparatus for installing an

electrical conductor (i.e., a cable) in a drill string having conventional, non-wired drill pipe.

U.S. Patent No. 2,379,800 to Hare, European Patent Application No. 399,987 to Wellhausen, and Russian Federation Patent No. 2,040,691 to Kononov et al. all describe signal transmission systems that employ inductive couplings with WDP. International Patent Application No. WO 02/06716 to Hall also discloses a system for transmitting data through a string of WDP joints using inductive couplers.

For downhole drilling operations, a large number of drill pipe joints are used to form a chain between the surface kelly joint (or, alternatively, the power swivel in top-drive drilling) and a drill bit. This chain of drill pipe joints substantially makes up the body of a drill string (although a drill string includes other components such as MWD tools, LWD tools, drill collars, stabilizers, bent sub, mud motor, bit box, and drill bit). A 15,000 ft (5472 m) well will typically have 500 drill pipe joints each having a length of 30 ft (9.14 m). In WDP operations, some or all of the drill pipe joints may be provided – especially by embedding within their walls – with conductive wires to form wired drill pipe (“WDP”) joints that are interconnected to provide a communication link between the surface and the drilling tool. With 500 drill pipe joints, also known simply as “pipes” or “tubes,” there are 1000 pipe ends/shoulders to be “made up” or connected by threaded rotation to other pipe joints, tubes, subs, etc. (collectively, “tubular members”). Each of these pipe ends may include communication couplers such as inductive couplers, particularly toroidal transformers.

The sheer number of connections in a drill string raises concerns of reliability for a WDP system. A commercial drilling system is expected to have a minimum mean time between system failures (MTBF) of about 500 hours or more. If one of the wired connections in a WDP system fails, then that communication link fails, whereby the entire telemetry system fails. Therefore, where there are 500 WDP joints in a 15,000 ft (5472 m) well, each WDP should have an MTBF of at least about 250,000 hr (28.5 yr) in order for the entire system to have an MTBF of 500 hr. This means that each WDP joint should have a failure rate of less than 4×10^{-6} per hr. This requirement is beyond the current WDP technology. Therefore, it is desirable, if not essential, to preemptively address the probability of failures in a WDP system.

Accordingly, it is desirable to possess a telemetry system capable of bypassing WDP-related failures.

It is further desirable to possess a telemetry system that employs WDP technology to advantage, in cooperation with non-wired drill string sections (e.g., non-wired drill pipe), particularly when such non-wired drill string section(s) are already in use.

It is further desirable to have a telemetry system capable of wireless communication at or near the surface to decrease the reliance upon wired systems in the upper portion of the drill string.

SUMMARY OF THE INVENTION

Certain terms are defined throughout this description as they are first used, while certain other terms used in this description are defined below:

“communicative” means capable of conducting or carrying a signal;

“communicative connection” means a connection between two adjacent tubular members, such as adjacent pipe joints, through which a signal may be conducted;

“communication link” means a plurality of communicatively-connected tubular members, such as interconnected WDP joints or adapter subs connected by a cable, for conducting a signal over a distance (“communication link” and “communication channel” are used synonymously herein);

“surface computer” means a computer, surface transceiver, and/or other components for processing data conveyed by way of signals;

“telemetry system” means at least one communication link plus other components such as a surface computer, MWD/LWD tools, communication subs, and/or routers, required for the measurement, transmission, and indication/recording of data acquired from or through a wellbore.

In one aspect, the present invention provides a cabled communication link for a drill string, and includes at least two adapter subs spaced apart within the drill string by a distance that exceeds the length of three interconnected drill pipe joints. A cable connects the two adapter subs for communication of a signal therebetween.

In a preferred embodiment, each of the adapter subs of the cabled communication link includes a communicative coupler intermediate its ends, and an inner annular recess spaced a predetermined axial distance from the communicative coupler. The cable carries a pair of sub connectors that are connected in series along the cable. Each of the sub connectors has a complementing communicative coupler, whereby alignment of a sub connector’s complementing communicative coupler with the communicative coupler of an adapter sub establishes communication between the

adapter sub and sub connector. The communicative couplers and complementing communicative couplers are preferably inductive couplers. The second of the pair of sub connectors similarly engages a second adapter sub. In this manner, a signal may be transmitted between the cable and the drill string.

Each of the adapter subs preferably includes an inner annular recess spaced a predetermined axial distance from the communicative coupler. Each of the sub connectors preferably has a latch for engaging the inner annular recess of one of the adapter subs and positioning its complementing communicative coupler in alignment with the communicative coupler of the one adapter sub.

It is further preferred that the latch of each of the sub connectors includes a locking dog having at least one key for engaging the inner annular recess of one of the adapter subs. The key is spaced from the complementing communicative coupler of each sub connector by the predetermined axial distance. Thus, engagement by the key with the annular recess of one of the adapter subs when the cable is disposed within the drill string aligns the sub connector's complementing communicative coupler with the communicative coupler of the one adapter sub and establishes communication therebetween. The locking dog preferably includes a detent latch.

The inventive cabled communication link may be applied to advantage in a drill string wherein a plurality of WDP joints are interconnected within the drill string between the two adapter subs to form a piped communication link. In this application, the cabled communication link establishes an alternative pathway to the piped communication link for transmitting a signal through the drill string, whereby a failure in the piped communication system (i.e., the WDP system) may be bypassed.

The cabled communication link may also be used to advantage in a drill string wherein a non-wired section of the drill string is disposed between the two adapter subs. In this manner, the cabled communication link establishes a pathway for transmitting a signal through the non-wired section of the drill string, whereby the non-wired section is converted to a cabled section. The non-wired section of the drill string may include one or more non-wired drill pipe joints or one or more non-wired utility subs.

In another aspect, the present invention provides a telemetry system for a drill string disposed within a wellbore and having a plurality of WDP joints that form a first communication link. Each of the WDP joints has a communicative first coupler at or near each end thereof, and a first cable connecting the communicative first couplers. The drill string further includes a pair of adapter subs spaced apart within the drill string

by a distance that exceeds the length of three interconnected drill pipe joints. Each of the adapter subs has a communicative second coupler at or near at least one of the adapter sub's ends, and is adapted for connection to a second cable disposed in the drill string such that a second cable connects the pair of adapter subs to form a second communication link. At least one of the adapter subs is connected in the drill string such that its communicative second coupler is adjacent a communicative first coupler of one of the WDP joints to couple the one adapter sub to the one WDP joint for communication therebetween. In this manner, the first communication link may be coupled for communication with a second communication link to transmit signals through the drill string.

In one embodiment of the inventive telemetry system, the one adapter sub is connected between two of the WDP joints within the drill string, whereby a portion of the first communication link may be bypassed by a second communication link. Alternatively, the one adapter sub may be connected between the one WDP joint and a non-wired section of the drill string, whereby the non-wired section of the drill string may be converted to a cabled section by a second communication link. In the alternative embodiment, the non-wired section of the drill string may include one or more non-wired drill pipe joints and/or non-wired utility subs.

It is preferred that the communicative first couplers of the WDP joints and the communicative second couplers of the adapter subs are inductive couplers.

A preferred embodiment of inventive telemetry system contemplates, and is adapted for use with, a second cable disposed within the drill string for connecting the pair of adapter subs to form a second communication link coupled for communication with the first communication link. For this purpose, each of the adapter subs includes a communicative third coupler intermediate the communicative second couplers, and an inner annular recess spaced a predetermined axial distance from the communicative third coupler. The second cable has a pair of sub connectors carried in series thereby, and each of the sub connectors has a communicative fourth coupler, whereby alignment of the sub connector's communicative fourth coupler with the communicative third coupler of the one adapter sub establishes communication between the first communication link and the second communication link. In this manner, a signal may be transmitted between the second cable and the drill string. The communicative third couplers and communicative fourth couplers are preferably inductive couplers.

Each of the adapter subs preferably includes an inner annular recess spaced a predetermined axial distance from the communicative third coupler. Each of the sub connectors preferably has a latch for engaging the inner annular recess of an adapter sub and positioning its communicative fourth coupler in alignment with the communicative third coupler of the engaged adapter sub.

It is further preferred that the latch of each of the sub connectors includes a locking dog having at least one key for engaging the inner annular recess of one of the adapter subs. The key is spaced from the communicative fourth coupler of each sub connector by the predetermined axial distance. Thus, engagement by the key with the annular recess of an adapter sub when the cable is disposed within the drill string aligns the sub connector's communicative fourth coupler with the communicative third coupler of the engaged adaptor sub and establishes communication therebetween. The locking dog may include a detent latch.

The inventive telemetry system contemplates the use of a plurality of adapter subs (i.e., not merely two) spaced apart within the drill string by a distance that exceeds the length of three interconnected drill pipe joints. Each of the adapter subs is adapted for connecting to – and includes in a preferred embodiment – a second cable disposed within the drill string such that a second cable can connect at least two of adapter subs to form a second communication link. At least one of the adapter subs is connected in the drill string such that its communicative second coupler is adjacent a communicative first coupler of one of the WDP joints to couple the one adapter sub to the one WDP joint for communication therebetween. The first communication link may therefore be coupled for communication with a second communication link.

In a preferred embodiment, the inventive telemetry system further includes a measurement tool disposed in a lower section of the drill string, a surface computer for processing data acquired by the measurement tool, a first communication sub disposed in or above an upper section of the drill string for communicating with the surface computer, and a second communication sub disposed in the lower section of the drill string for communicating with the measurement tool. The first communication link provides at least a portion of an operative communicative connection between the downhole communication sub and the surface communication sub. A second cable may be disposed within the drill string and connected across the pair of adapter subs, thereby forming a second communication link connected for communication with the first communication link. The second communication link also provides at least a portion of

an operative communicative connection between the second communication sub and the first communication sub.

This embodiment contemplates that the measurement tool, e.g., an MWD/LWD tool, may also serve as an adapter sub.

In various embodiments of the telemetry system, the first communication sub is disposed: beneath a kelly joint in the (rotary table-driven) drill string; above a kelly joint in the (rotary table-driven) drill string; beneath a power swivel supporting the (top-driven) drill string; or within a power swivel supporting the (top-driven) drill string. If disposed above a kelly joint in the drill string, the first communication sub may include a rotary transformer or a slip ring. The first communication sub may also include, in various applications, a first wireless transceiver in wired communication with the first communication link. The first wireless transceiver is preferably complemented by a second wireless transceiver in wired communication with the surface computer, and the first and second wireless transceivers are adapted for wireless communication therebetween. The second wireless transceiver may be disposed in a mud return line connected between a mud pit and the wellbore.

In another aspect, the first communication sub of the inventive telemetry system includes a WDP modem in wired communication with the first communication link, a wireless modem in wired communication with the WDP modem, and a power supply powering the modems. The power supply may include one or more batteries.

In yet another aspect, the present invention provides a telemetry system for a drill string having a plurality of interconnected drill pipe joints suspended by a derrick and engaged by a torque-applying mechanism for rotation thereof. A measurement tool is suspended by the drill pipe joints for acquiring wellbore data, a downhole communication sub is suspended by the drill pipe joints for communicating with the measurement tool via the drill pipe joints, and a drill bit defines the lower end of the drill string. The system includes a surface computer for processing data acquired by the measurement tool, and a surface communication sub disposed in the drill string beneath a portion of the drill string engaged by the torque-applying mechanism for wirelessly-communicating with the surface computer. The surface communication sub communicates with the downhole communication sub (at least partially) via the drill pipe joints.

In a preferred embodiment according to this aspect of the present invention, the surface communication sub includes a first wireless transceiver, and the telemetry

system further includes a second wireless transceiver disposed in a mud return line connected between a mud pit and the wellbore. The second wireless transceiver is in wired communication with the surface computer. The downhole communication sub may communicate with the surface communication sub in a number of ways, including mud-pulse telemetry, electromagnetic telemetry, pipe acoustic telemetry, and wired links. One example of such a wired link is embodied by using sequentially-connected WDP joints for at least some of the drill pipe joints, the WDP joints having a first communication link therethrough providing at least a portion of an operative communicative connection between the downhole communication sub and the surface communication sub.

In a particular embodiment, the inventive telemetry system further includes a means for forming a second communication link coupled for communication with the first communication link. In this embodiment, each of the WDP joints has communicative first couplers at or near both ends thereof, and a first cable connecting the communicative first couplers. The second communication link-forming means preferably includes a pair of adapter subs spaced apart within the drill string by a distance that exceeds the length of three interconnected drill pipe joints. Each of the adapter subs has a communicative second coupler at or near at least one of its ends. The adapter subs are adapted for connection to a second cable disposed within the drill string – which the invention also contemplates – such that a second cable connects the pair of adapter subs to form a second communication link. At least one of the adapter subs is connected in the drill string such that its communicative second coupler is adjacent a communicative first coupler of one of the WDP joints to couple the one adapter sub to the one WDP joint for communication therebetween. In this manner, the first communication link may be coupled for communication with a second communication link to transmit signals through the drill string.

This embodiment also contemplates that the measurement tool, e.g., an MWD/LWD tool, may also serve as an adapter sub.

It is further preferred in this aspect of the invention that each of the adapter subs includes a communicative third coupler intermediate the communicative second couplers. The second cable has a pair of sub connectors carried in series thereby. Each of the sub connectors has a communicative fourth coupler, whereby alignment of the sub connector's communicative fourth coupler with the communicative third coupler of an adapter sub establishes communication therebetween.

In a still further aspect, the present invention provides a downhole drilling method that includes the steps of drilling a wellbore with a drill string, acquiring wellbore data while drilling with a measurement tool disposed in the drill string, and transmitting the acquired wellbore data to the surface of the wellbore via a communication link defined by at least two adapter subs spaced apart within the drill string by a distance that exceeds the length of three interconnected drill pipe joints. A cable connects the adapter subs for transmitting signals between the adapter subs.

In a particular embodiment, the inventive downhole drilling method further includes the step of transmitting the acquired wellbore data to the surface of the wellbore via another communication link defined by a plurality of interconnected WDP joints, and the step of transmitting the acquired wellbore data to the surface of the wellbore via a third communication link defined by a surface communication sub wired for communication to the interconnected WDP joints. The surface communication sub transmits the acquired wellbore data from the interconnected WDP joints to a surface computer for processing, and may use one or more wireless transceivers for this purpose.

In a still further aspect, the present invention relates to a downhole drilling method that includes the steps of drilling a wellbore with a drill string, acquiring wellbore data while drilling with a measurement tool disposed in the drill string, and transmitting the acquired wellbore data to the surface of the wellbore via a first communication link defined by a plurality of WDP joints and a second communication link defined by at least a pair of spaced apart adapter subs connected by a second cable for communication of signals between the pair of adapter subs.

In a particular embodiment of this drilling method, the transmitting step includes using the second communication link to bypass a portion of the first communication link. Alternatively, the step of transmitting may include using the second communication link to convert a non-wired section of the drill string into a cabled section.

In yet a further aspect, the invention provides a downhole drilling method that includes the step of drilling a wellbore with a drill string having a plurality of adapter subs disposed therein. Successive adapter subs within the drill string are separated by at least four interconnected wired drill pipe joints. The adapter subs and wired drill pipe joints together define a first communication link. Wellbore data is acquired while drilling with a measurement tool disposed in the drill string, and the acquired wellbore

data is transmitted to the surface of the wellbore via the first communication link. Upon detecting the presence of a fault in the first communication link, a cable is disposed within the drill string for establishing a second communication link. The cable has a pair of spaced sub connectors connected in series along the cable for establishing communication with a respective pair of consecutive adapter subs, whereby the second communication link is established by such communication. The second communication link bypasses the interconnected wired drill pipe joints between the pair of consecutive adapter subs.

In a preferred embodiment of the invention according to this method, a determination is made whether the fault lies within the portion of the drill string between the pair of consecutive adapter subs. Upon determining that the fault does not lie within the portion of the drill string between the pair of consecutive adapter subs, the cable is moved within the drill string to establish communication between the pair of sub connectors and other respective pairs of consecutive adapter subs until the location of the fault is identified. Once the fault is identified, it may be cured, e.g., by replacing defective joints of wired drill pipe during a trip of the drill string.

Other aspects of the invention will become apparent from the following description, the drawings, and the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1A is an elevational representation of a drill string having a telemetry system that includes a piped communication link and a cabled communication link in accordance with one aspect of the present invention;

Figure 1B shows a detailed portion of the drill string of Figure 1, illustrating in particular the use of the cabled communication link as a bypass for a failure in the piped communication link;

DETAILED DESCRIPTION

Figure 1A depicts a drill string 6 that employs a telemetry system 100 in accordance with one aspect of the present invention. The drill string 6 includes a plurality of interconnected tubular members (described further below) suspended from a derrick and platform assembly 10 by way of a traveling block (not shown) and a hook 18. The upper end of the drill string 6 is defined by a kelly joint 17, the uppermost tubular member in the string, which is engaged by a conventional torque-applying means including a rotary table 16 for rotating the kelly joint as well as the entire drill

string 6. A swivel 19 connects the hook 18 to the kelly joint 17, and permits rotation of the kelly joint and the drill string 6 relative to the hook.

The lower end of the drill string is defined by a drill bit 15 which drills through the formation F to create a wellbore 7. The drill bit is connected for rotation with the drill string 6 in a rotary drilling configuration of the sort described above.

The drill string 6 may otherwise employ a "top-drive" configuration (also well known) wherein a power swivel rotates the drill string instead of a kelly joint and rotary table. Those skilled in the art will also appreciate that "sliding" drilling operations may otherwise be conducted with the use of a well known Moineau-type mud motor that converts hydraulic energy from the drilling mud pumped from a mud pit down through the drill string 6 into torque for rotating a drill bit. Drilling may furthermore be conducted with so-called "rotary-steerable" systems which are known in the related art. The various aspects of the present invention are adapted to each of these configurations and are not limited to conventional rotary drilling operations, although such equipment and methods will be described herein for illustrative purposes.

With reference now to Figures 1A-1C and 2A, the drill string telemetry system 100 includes a cabled communication link 5b having at least two spaced apart adapter subs (e.g., 9a, 9b, 9c) within the drill string and a cable 112 connecting the two adapter subs 9a, 9b for communication of a signal therebetween. As shown particularly in Figures 2A-2B, each of the adapter subs (indicated simply as 9) of the cabled communication link 5b includes a communicative coupler 114 intermediate its ends, and an inner annular recess 116 spaced a predetermined axial distance d1 from the communicative coupler 114. The communicative coupler 114 is wired for communication through a cable 115, permitting the adapter sub 9 to also serve as a component in a piped communication link 5a (described further below).

The cable 112 includes a load-bearing, protective skin 113 and at least a pair of wires 112a, 112b along its length. The cable 112 also carries, by way of mechanical and communicative connection, a pair of generally cylindrical sub connectors 118 that are spaced apart and connected to each other in series via the cable skin 113 and communicative wires 112a, 112b. Each of the sub connectors 118 has a complementing communicative coupler 120 connected by the cable wires 112a, 12b, and a locking dog 122 having at least one key 124 biased outwardly by a coil spring 126 for engaging the annular recess 116 of one of the adapter subs 9. Those skilled in the art will appreciate that other known mechanical means for positively engaging a cable-conveyed tool to a

tubular member in a drill string may be used to advantage, such as the detent latch mechanism disclosed in U.S. Patent No. 5,971,072 to Huber et al., the keyed anchoring system disclosed in U.S. Patent No. 4,901,060 to Veneruso, as well as other known latching means (e.g., frictional brake/lock, roller brake, magnetic lock).

The locking dog preferably uses a "detent" latch that permits engagement and disengagement by the application of a predetermined force. In the case of engagement, the requisite force is applied by the weight of the cable 112 and sub connector(s) 118. For disengagement, the requisite force is applied by tension in the cable 112 from a wireline unit mounted on a truck, trailer, or platform at the surface.

The key 124 is spaced along the sub connector 118 from the complementing communicative coupler 120 by the predetermined axial distance $d1$. In this configuration, when the cable 112 is disposed within the drill string to lower one or more sub connectors 118 within adapter subs 9, engagement by the key 124 of one of the sub connectors 118 with the annular recess 116 of one of the adapter subs 9 vertically aligns the sub connector's complementing communicative coupler 120 with the communicative coupler 114 of the one adapter sub 9 to establish communication between the one adapter sub 9 and the sub connector 118. In this manner, a signal may be transmitted between the cable 112 and the drill string 6 containing the adapter sub 9. The communicative coupler 114 and complementing communicative coupler 120 are preferably inductive couplers, as are known in the art (see also the related description below).

Those skilled in the art and given the benefit of this disclosure will appreciate that effective communication may also be established by passive positioning using only the cable 112. In other words, the use of positive latching means for positioning the sub connector 118 within the adapter sub 9 is not an essential feature of the present invention, although such means are presently preferred.

Figure 2B illustrates the connector sub 118 being equipped with an electronics package 119 for performing one or more functions such as switching, signal amplification, impedance matching, or signal modulation/demodulation.

With particular reference now to Figure 1B, the cabled communication link 5b may be applied to advantage in a drill string 6 wherein a plurality of WDP joints 8 are interconnected within the drill string between two adapter subs 9a, 9b to form a piped communication link 5a. In this application, the cabled communication link 5b establishes an alternative pathway to the piped communication link 5a for transmitting a

signal through the drill string 6. Thus, when a failure in the piped communication system (i.e., the WDP system) occurs at WDP joint 8f, drill string telemetry is maintained by establishing the cabled communication link 5b as described herein.

Figure 1C demonstrates the cabled communication link 5b being used to advantage in a drill string wherein a non-wired section NW of the drill string 6 is disposed between the two adapter subs 9a', 9b'. In this manner, the cabled communication link 5b establishes a pathway for transmitting a signal through the non-wired section NW of the drill string, whereby the non-wired section is converted to a cabled section. The non-wired section of the drill string may include one or more standard (i.e., non-wired) drill pipe joints 4 or, alternatively, one or more non-wired utility subs such as drill collars, stabilizers, jars, bent subs, etc. In this sense, the cabled communication link (also referred to herein as a second communication link) establishes a so-called "hybrid" telemetry system.

The piped communication link (also referred to herein as a first communication link) 5a established by the plurality of wired drill pipe (WDP) joints will now be described in greater detail. One type of WDP joint, as disclosed in U.S. Patent Application No. 2002/0193004 by Boyle et al. and assigned to the assignee of the present invention, uses communicative first couplers – preferably inductive couplers – to transmit signals across the WDP joints. An inductive coupler in the WDP joints, according to Boyle et al., comprises a transformer that has a toroidal core made of a high permeability, low loss material such as Supermalloy (which is a nickel-iron alloy processed for exceptionally high initial permeability and suitable for low level signal transformer applications). A winding, consisting of multiple turns of insulated wire, winds around the toroid core to form a toroid transformer. In one configuration, the toroidal transformer is potted in rubber or other insulating materials, and the assembled transformer is recessed into a groove located in the drill pipe connection.

Turning now to Figures 3-5, a WDP joint 210 is shown to have communicative first couplers 221, 231 at or near the respective end 241 of box end 222 and the end 234 of pin end 232 thereof. A first cable 214 extends through a conduit 213 to connect the communicative first couplers, 221, 231 in a manner that is described further below. The WDP joint 210 is equipped with an elongated tubular shank 211 having an axial bore 212, a box end 222, a pin end 232, and a first cable 214 running from the box end 222 to the pin end 232. A first current-loop inductive coupler element 221 (e.g., a toroidal transformer) and a similar second current-loop inductive coupler element 231

are disposed at the box end 222 and the pin end 232, respectively. The first current-loop inductive coupler element 221, the second current-loop inductive coupler element 231, and the first cable 214 collectively provide a communicative conduit across the length of each WDP joint. An inductive coupler (or communicative connection) 220 at the coupled interface between two WDP joints is shown as being constituted by a first inductive coupler element 221 from WDP joint 210 and a second current-loop inductive coupler element 231' from the next tubular member (which may be another WDP joint, or an adapter sub 9a as described above). Those skilled in the art will recognize that, in some embodiments of the telemetry system 100, the inductive coupler elements may be replaced with other devices serving a similar communicative function, such as, e.g., direct electrical-contact connections of the sort disclosed in U.S. Patent No. 4,126,848 by Denison.

Figures 4 and 5 depict the inductive coupler or communicative connection 220 of Figure 3 in greater detail. Box end 222 includes internal threads 223 and an annular inner contacting shoulder 224 having a first slot 225, in which a first toroidal transformer 226 is disposed. The toroidal transformer 226 is connected to the cable 214. Similarly, pin-end 232' of an adjacent wired tubular member (e.g., another WDP joint or an adapter sub 9a) includes external threads 233' and an annular inner contacting pipe end 234' having a second slot 235', in which a second toroidal transformer 236' is disposed. The second toroidal transformer 236' is connected to a second cable 214' of the adjacent tubular member 9a. The slots 225 and 235' may be clad with a high-conductivity, low-permeability material (e.g., copper) to enhance the efficiency of the inductive coupling.

When the box end 222 of one WDP joint is assembled with the pin end 232' of the adjacent tubular member (e.g., another WDP joint or an adapter sub 9a), a communicative connection is formed. Figure 5 shows a cross section of a portion of the resulting interface, in which a facing pair of inductive coupler elements (i.e., toroidal transformers 226, 236') are locked together to form a communicative connection within an operative communication link. This cross section view also shows that the closed toroidal paths 240 and 240' enclose the toroidal transformers 226 and 236', respectively, and conduits 213 and 213' form passages for internal electrical cables 214 and 214' that connect the two inductive coupler elements disposed at the two ends of each WDP joint.

The above-described inductive couplers incorporate an electric coupler made with a dual toroid. The dual-toroid coupler uses inner shoulders of the pin and box ends as electrical contacts. The inner shoulders are brought into engagement under extreme pressure as the pin and box ends are made up, assuring electrical continuity between the pin and the box ends. Currents are induced in the metal of the connection by means of toroidal transformers placed in slots. At a given frequency (for example 100 kHz), these currents are confined to the surface of the slots by skin depth effects. The pin and the box ends constitute the secondary circuits of the respective transformers, and the two secondary circuits are connected back to back via the mating inner shoulder surfaces.

While Figures 3-5 depict certain communicative coupler types, it will be appreciated by one of skill in the art that a variety of couplers may be used for communication of a signal across interconnected tubular members. For example, such systems may involve magnetic couplers, such as those described in International Patent Application No. WO 02/06716 to Hall. Other systems and/or couplers are also envisioned.

In Figure 3, the spacing between adapter subs 9a, 9b is illustrated as being only one joint of WDP, i.e., 30 feet (9.144 m), for simplicity. Those skilled in the art will appreciate, however, that such spacing will often be defined a plurality of interconnected WDP joints, and, in one embodiment, is presently intended to be approximately 1000 feet (304.8 m) in length. A string of WDP joints of this length is believed to be operative without the need for repeater or booster subs to enhance the communicated signal(s) over extended distances, but the present invention is well adapted for, and contemplates the use of, such repeaters as needed. The adapter subs are themselves very similar to the WDP joints described herein, except the adapter subs may have a differing lengths than the standard 30 foot (9.144 m) joint length – particularly shortened lengths, down to as little as 3 feet (0.914 m) – and the adapter subs are adapted for engagement with a second cable 112 as described above with reference to Figures 2A and 2B. Furthermore, measurement tools M disposed in the drill string, such as MWD and LWD tools, may be equipped to also function as adapter subs, permitting the direct connection of a cable such as cable 112 (described below) to one or more measurement tools M.

Each of the adapter subs 9a, 9b in Figure 3 has a communicative second coupler 231', 221' at or near at least the respective end 234' of pin end 232' and the end 241' of

box end 222' thereof. The adapter subs are adapted for connection to a second cable 112 disposed in the drill string 6 such that the second cable 112 connects the pair of adapter subs to form a second communication link 5b, as described above. It is intended that the second communication link will only be established as needed, e.g., to "jump" or bypass a failure in the first communication link, or to establish a communication link in a portion of the drill string where none exists.

Thus, in the embodiment of the inventive telemetry system shown in Figures 2A-B, the one adapter sub 9 is connected between two of the WDP joints 8 within the drill string 6, whereby a portion of the first communication link 5a defined by interconnected WDP joints (and including adapter sub 9) may be bypassed by a second communication link 5b defined by cable-wired adapter subs. Alternatively, the one adapter sub 9 may be connected between one of the WDP joints and a non-wired section of the drill string (see, e.g., Figure 1C), whereby the non-wired section of the drill string may be converted to a cabled section by a second communication link. In the alternative embodiment, the non-wired section of the drill string may include one or more non-wired drill pipe joints and/or non-wired utility subs.

The inventive telemetry system of the present invention contemplates the use of a plurality of adapter subs 9 (i.e., not merely two) preferably disposed at the above-mentioned spacing interval of 1000 feet (304.8 m) within the drill string. Each of the adapter subs 9 is adapted for connecting to a second cable 112 disposed within the drill string 6, as described above with reference to Figures 2A-B. In this manner, the spaced adapter subs serve dual purposes: (1) a conduit in the first communication link 5a defined by WDP joints; and (2) as "jumpers" ready to bypass or jump across, e.g., one or more defective WDP joints in the first communication link 5a, as needed.

In most embodiments (see Figure 1A), the telemetry system 100 will further include one or more measurement tools M disposed in a lower section of the drill string 6 known as a bottom hole assembly (BHA) 200. Also included is a surface computer 2 for processing data acquired by the measurement tool(s) M, and a first communication sub 70 disposed in or above an upper section of the drill string (above kelly joint 17) for communicating with the surface computer 2. The first communication sub 70, also known as a surface communication sub, also communicates with the first communication link 5a and the second communication link 5b by connection means that are known in the art. The telemetry system 100 further includes a second communication sub 80, also known as a downhole communication sub, disposed in a

lower section of the drill string 6 just above the BHA 200 for communicating with (at least) the measurement tool(s) M. The first communication link 5a provides at least a portion of an operative communicative connection between the downhole communication sub 80 and the surface communication sub 70. A second cable 112 may be disposed within the drill string 6 and connected across a pair of adapter subs 9, thereby forming the second communication link 5b (or a part thereof) connected for communication with the first communication link 5a. The second communication link 5b thus provides at least a portion of an operative communicative connection between the downhole communication sub 80 and the surface communication sub 70, e.g., as a bypass or supplement to link 5a.

In various embodiments of the telemetry system, the first (or surface) communication sub 70 is located according to one of four configurations: beneath the kelly joint 17 in the (rotary table-driven) drill string 6; above the kelly joint in the (rotary table-driven) drill string; beneath a power swivel supporting the (top-driven) drill string (not shown); or within a power swivel supporting the (top-driven) drill string (not shown). If disposed above a kelly joint in the drill string, the first communication sub may include a slip ring or a rotary transformer for communicating signals between the rotating drill string 6 and the stationary surface components of the telemetry system 100.

The top-driven drill string is similar to the rotary table-drive drill string 6 depicted in Figure 1A, except the rotary table 16 and swivel 19 are replaced with a power swivel that supports and rotates the drill string.

A slip ring (also known as brush contact surfaces) is a well known electrical connector designed to carry current or signals from a stationary wire into a rotating device. Typically, it is comprised of a stationary graphite or metal contact (a brush) carried in a non-rotating component 1 (e.g., within swivel 19) which rubs on the outside diameter of a rotating metal ring (e.g., carried on the upper portion of kelly joint 17). As the metal ring turns, the electrical current or signal is conducted through the stationary brush to the metal ring making the connection. Plural ring/brush assemblies may be stacked along the rotating axis if more than one electrical circuit is needed.

Rotary electrical couplings based on induction (transformer action), known as rotary transformers, provide an alternative to slip rings and contact brushes based upon conduction between rotating and stationary circuitry. Thus, no direct contact is necessary for transformer action to occur in an inductive rotary coupling. Figure 6

shows a simplified cross section of a typical inductive rotary coupling between a stationary circuit 72 mounted within a stationary housing 1 and a rotating circuit (which includes communication links 5a and/or 5b) mounted on the kelly joint 17. The transformer windings comprise a stationary coil 74 and a rotating coil 76, both concentric with the axis of rotation. Either coil can serve as the primary winding, with the other serving as the secondary winding. The stationary assembly includes a transformer core that, like a conventional stationary power transformer, is made by stacking sheets of silicon steel or other suitable magnetically "soft" material, except the core has an inner portion 77 and an outer portion 78 that define a shape to accommodate the rotating parts. The hollow shaft accommodates the wires that connect the rotating coil with the rotating circuit at one end of the shaft.

As mentioned above, the drillstring 6 typically includes a bottom hole assembly (BHA) 200 disposed near the drill bit 15. The BHA 200 may include capabilities for measuring, processing, and storing information, as well as communicating with the surface (e.g., MWD/LWD tools) via a downhole communication sub 80. An example of a measurement tool M having such capabilities for resistivity determination is described in detail in U.S. Patent No. 5,339,037.

A signal representing one or more measurements from the BHA 200 is transmitted up the drill string 6 from measurement tool(s) M via downhole communication sub 80. Transmission may be achieved by conventional means, such as mud-pulse telemetry, electromagnetic telemetry, and pipe acoustic telemetry, or, more advantageously, by communication links 5a, 5b as described herein. The transmitted signal is received by surface communication sub 70 which, in certain embodiments, employs means coupled to the kelly joint 17 such as a slip ring or rotary transformer 1 for communicating the signal from a rotating circuit to a stationary circuit within swivel 19. The stationary circuit of the transformer or slip ring is coupled via a wired connection, such as cable 3, to a surface computer 2 for processing and storage/display. The surface computer 2 also provides for communication with, and control of, measurement tool(s) M via appropriate signals directed back down the drill string 6. The rotating circuit of the rotary transformer or slip ring is also coupled to the downhole communication sub 80 via the communication links 5a, 5b, described above, extending through the drill string 6.

Figure 7A shows a schematic representation of an alternative telemetry system 100a having a surface wireless communication link instead of the wired couplers

described above. The telemetry system 100a is essentially the same as the telemetry system 100 of Figure 1A, except that a surface communication sub 70a is operatively coupled to the kelly 17 in place of the surface communication sub 70 having the rotary transformer or slip ring. In this embodiment, a wireless connection 3a exists between the surface computer 2a and the surface communication sub 70a. The surface communication sub 70a is operatively connected to the downhole communication sub 80a via the communication links 5a, 5b as previously described.

The surface communication sub 70a includes a WDP modem 315 in wired communication with the first communication link 5a, a wireless modem 325 in wired communication with the WDP modem 315, and a power supply 310 powering the modems. The power supply may include one or more batteries 305.

The surface communication sub 70a is preferably a short adapter sub, or a WDP surface communication sub, which provides an interface between the wireless communication link and the piped communication link (also referred to herein as the first communication link) 5a.

WDP modem 315 enables communication between the surface communication sub 70a and the piped communication link 5a of the WDP system. The wireless modem 325 enables communication between the surface communication sub and the surface computer via the wireless connection 3a. The WDP modem and the wireless modem are operatively coupled by a high-speed link 320. The surface communication sub 70a and the surface computer 2a are each provided with respective wireless transceivers 325t, 2t capable of wirelessly sending and receiving signals therebetween via the wireless connection 3a.

Figure 7B shows a schematic representation of a conventional downhole communication sub 80a employing aspects of the present invention. Sub 80a includes a WDP modem 95 for communicating through the piped communication link 5a, 5b with the surface communication sub 70a. WDP modem 95 is wired for high speed communications with bus network interface 105, which is in turn communicatively connected with the BHA 200. A power supply 90 powers the downhole communication sub 80a, and may include one or more batteries 85.

The telemetry system represented collectively by Figures 7A and 7B enables a wireless communication link (also referred to herein as a third communication link) at the surface to cooperate with piped and/or cabled communication links in the wellbore.

Figure 8 shows yet another embodiment of the telemetry system, labeled 100b, wherein a surface communication sub 70b is disposed in the drill string beneath a portion of the drill string engaged by the torque-applying mechanism (e.g., beneath rotary table 16) for wirelessly-communicating with the surface computer 2b. The surface communication sub 70b includes a first wireless transceiver 71, and the telemetry system further includes a second wireless transceiver 91 disposed in a mud return line 90 connected between a mud pit 92 and the wellbore. It is desirable for the transceiver 91 to be positioned as closely as possible to the drill string 6, and the location of the transceiver 91 along the mud return line 90 is not essential. Thus, alternative locations, such as a nearby riser or casing pipe joint, may be similarly employed to advantage. The second wireless transceiver 91 is in wired communication with the surface computer 2b via cable 3b. The downhole communication sub 80 may communicate with the surface communication sub 70b in a number of ways, including conventional mud-pulse telemetry and wired links – particularly according to communication links 5a, 5b.

The present invention further provides a method of downhole drilling 400 that employs the telemetry systems described above to advantage. Thus, with reference particularly to Figure 9 and generally to the other figures, the method 400 includes the steps of drilling a wellbore with a drill string 6 (step 410), acquiring wellbore data with a measurement tool M disposed in the drill string 6 while drilling (step 430), and transmitting the acquired wellbore data to the surface of the wellbore via a cabled communication link 5b (step 490). The cabled communication link 5b is defined by at least two spaced apart adapter subs 9 disposed within the drill string 6 and a cable 112 connecting the adapter subs for transmitting signals between the adapter subs (step 420), as described herein.

The downhole drilling method 400 further includes the step of transmitting the acquired wellbore data to the surface of the wellbore via another communication link 5a defined by a plurality of interconnected WDP joints 8 (step 440: “yes” to step 450), and the step of transmitting the acquired wellbore data to the surface of the wellbore via a third communication link defined by a surface communication sub 70/70a/70b (step 500) wired for communication to the interconnected WDP joints 8. The surface communication sub 70/70a/70b transmits the acquired wellbore data from the interconnected WDP joints 8 to a surface computer 2/2a for processing, and may use one or more wireless transceivers 71, 91 for this purpose (refer, e.g., to Figure 8).

The transmitting step 490 is enabled by using the second communication link 5b to bypass a portion of the first communication link 5a (step 470) once a failure has been attributed to the first communication link 5a (step 460), or alternatively, to convert a non-wired section NW of the drill string into a cabled section (step 480).

The identification of a failure in the WDP system (step 460) may be achieved by passing a signal through the first communication link 5a, and then measuring the signal to determine the voltage and/or current, and the impedance. By analyzing the impedance, the fault location may be determined. In particular, the impedance may have a ripple or strong resonance which indicates a fault. The received signal may also be measured in the time domain. The delay of the signal between the transmission and receipt may be analyzed to determine the location of a fault by indicating the distance the signal travels. This information may also be used to determine the number of failed WDP joints.

Figure 10, as well as the other figures in general, illustrate yet a further aspect of the present invention in the form of a downhole drilling method 600. A wellbore is drilled (step 610) with a drill string 6 having a plurality of adapter subs 9 disposed therein. Successive adapter subs within the drill string are separated by at least four interconnected wired drill pipe joints 8. The adapter subs 9 and wired drill pipe joints 8 together define a first communication link 5a (step 620). Wellbore data is acquired while drilling with a measurement tool M disposed in the drill string 6 (step 630), and the acquired wellbore data is transmitted to the surface of the wellbore via the first communication link 5a (step 640).

Upon detecting the presence of a fault in the first communication link 5a (step 650: YES), e.g., due to inability to communicate with the measurement tool M, a cable 112 is disposed within the drill string 6 for establishing a second communication link 5b (step 660). The cable 112 has a pair of spaced sub connectors 118 connected in series along the cable for establishing communication with a respective pair of consecutive adapter subs 9, such as the lowest pair of adapter subs in the drill string 6. In this manner, the second communication link 5b is established by such communication. In other words, the pair of sub connectors 118 communicatively couple to the pair of respective adapter subs 9, as described in detail herein. The second communication link 5b bypasses the interconnected wired drill pipe joints 8 between the pair of consecutive adapter subs 9.

A determination is then made whether the fault lies within the portion of the drill string between the pair of consecutive adapter subs 9 connected via cable 112 (step 670). Upon determining that the fault does not lie within the portion of the drill string between the pair of cabled, consecutive adapter subs (step 670: NO), the cable is moved within the drill string to establish communication between the pair of sub connectors and other respective pairs of consecutive adapter subs (step 680) until the location of the fault is identified. Preferably, the cable is moved so as to bypass each successive interconnected string of wired drill pipe joints between consecutive adapter subs 9. Once the fault is identified, e.g., by the unsuccessful return of a test signal, the fault may be cured (step 690) by replacing defective joint(s) 8 of wired drill pipe during a trip of the drill string 6.

CLAIMS

1. A cabled communication link for a drill string, the link comprising:
at least two adapter subs spaced apart within the drill string by a distance that exceeds the length of three interconnected drill pipe joints; and
a cable connecting the two adapter subs for communication of a signal therebetween.
2. The link of claim 1, wherein each of the adapter subs includes a communicative coupler intermediate its ends, and the cable has a pair of sub connectors carried in series thereby, each of the sub connectors having a complementing communicative coupler, whereby alignment of a sub connector's complementing communicative coupler with the communicative coupler of an adaptor sub establishes communication therebetween.
3. The link of claim 2, wherein each of the adapter subs further includes an inner annular recess spaced a predetermined axial distance from the communicative coupler, and each of the sub connectors further has a latch for engaging the inner annular recess of one of the adapter subs and positioning its complementing communicative coupler in alignment with the communicative coupler of the one adapter sub.
4. The link of claim 3, wherein the latch of each of the sub connectors includes a locking dog having at least one key for engaging the annular recess of one of the adapter subs, the key being spaced from the complementing communicative coupler of each sub connector by the predetermined axial distance, whereby engagement by the key with the annular recess of one of the adapter subs when the cable is disposed within the drill string aligns the sub connector's complementing communicative coupler with the communicative coupler of the one adaptor sub and establishes communication therebetween.
5. The link of claim 4, wherein the locking dog includes a detent latch.
6. The link of claim 2, wherein the communicative couplers and complementing communicative couplers are inductive couplers.
7. The link of claim 1, wherein a plurality of wired drill pipe joints are interconnected within the drill string between the two adapter subs to form a piped communication link, whereby the cabled communication link establishes an alternative pathway to the piped communication link for transmitting a signal through the drill string.

8. The link of claim 1, wherein a non-wired section of the drill string is disposed between the two adapter subs, whereby the cabled communication link establishes a pathway for transmitting a signal through the non-wired section of the drill string.

9. The link of claim 8, wherein the non-wired section of the drill string includes one or more non-wired drill pipe joints.

10. The link of claim 8, wherein the non-wired section of the drill string includes one or more non-wired utility subs.

11. A telemetry system for a drill string disposed within a wellbore, the system comprising:

a plurality of wired drill pipe joints within the drill string that form a first communication link, each of the wired drill pipe joints having a communicative first coupler at or near each end thereof, and a first cable connecting the communicative first couplers; and

a pair of adapter subs spaced apart within the drill string by a distance that exceeds the length of three interconnected drill pipe joints, each of the adapter subs having a communicative second coupler at or near at least one of the adapter sub's ends, and being adapted for connection to a second cable disposed in the drill string such that a second cable connects the pair of adapter subs to form a second communication link, one of the adapter subs being connected in the drill string such that its communicative second coupler is adjacent a communicative first coupler of one of the wired drill pipe joints to couple the one adapter sub to the one wired drill pipe joint for communication therebetween, whereby the first communication link may be coupled for communication with a second communication link to transmit signals through the drill string.

12. The telemetry system of claim 11, wherein the one adapter sub is connected between two of the wired drill pipe joints within the drill string, whereby a portion of the first communication link may be bypassed by a second communication link.

13. The telemetry system of claim 11, wherein the one adapter sub is connected between the one wired drill pipe joint and a non-wired section of the drill string, whereby the non-wired section of the drill string may be converted to a cabled section by a second communication link.

14. The telemetry system of claim 13, wherein the non-wired section of the drill string includes one or more non-wired drill pipe joints.

15. The telemetry system of claim 13, wherein the non-wired section of the drill string includes one or more non-wired utility subs.

16. The telemetry system of claim 11, wherein the communicative first couplers of the wired drill pipe joints and the communicative second couplers of the adapter subs are inductive couplers.
17. The telemetry system of claim 11, further comprising a second cable disposed within the drill string for connecting the pair of adapter subs to form a second communication link coupled for communication with the first communication link.
18. The telemetry system of claim 17, wherein each of the adapter subs includes a communicative third coupler intermediate the communicative second couplers, and the second cable has a pair of sub connectors carried in series thereby, each of the sub connectors having a communicative fourth coupler, whereby alignment of the sub connector's communicative fourth coupler with the communicative third coupler of the one adapter sub establishes communication between the first communication link and the second communication link.
19. The telemetry system of claim 18, wherein each of the adapter subs further includes an inner annular recess spaced a predetermined axial distance from the communicative third coupler, and each of the sub connectors further has a latch for engaging the inner annular recess of an adapter sub and positioning its communicative fourth coupler in alignment with the communicative third coupler the engaged adapter sub.
20. The telemetry system of claim 18, wherein the latch of each of the sub connectors includes a locking dog having at least one key for engaging the inner annular recess of one of the adapter subs, the key being spaced from the communicative fourth coupler of each sub connector by the predetermined axial distance, whereby engagement by the key with the annular recess of an adapter sub when the cable is disposed within the drill string aligns the sub connector's communicative fourth coupler with the communicative third coupler of the engaged adaptor sub and establishes communication therebetween.
21. The telemetry system of claim 20, wherein the locking dog includes a detent latch.
22. The telemetry system of claim 18, wherein the communicative third couplers and the communicative fourth couplers are inductive couplers.
23. The telemetry system of claim 11, comprising a plurality of adapter subs disposed at spaced intervals within the drill string, each of the adapter subs being adapted for connecting to a second cable disposed within the drill string such that a

second cable can connect at least two of adapter subs to form a second communication link, one of the adapter subs being connected in the drill string such that its communicative second coupler is adjacent a communicative first coupler of one of the wired drill pipe joints to couple the one adapter sub to the one wired drill pipe joint for communication therebetween, whereby the first communication link may be coupled for communication with a second communication link.

24. The telemetry system of claim 23, further comprising a second cable disposed within the drill string for connecting the one adapter sub and at least one other of the plurality of adapter subs to form a second communication link coupled for communication to the first communication link.

25. The telemetry system of claim 11, further comprising:

- a measurement tool disposed in a lower section of the drill string;

- a surface computer for processing data acquired by the measurement tool;

- a first communication sub disposed in or above an upper section of the drill string for communicating with the surface computer; and

- a second communication sub disposed in the lower section of the drill string for communicating with the measurement tool;

- the first communication link providing at least a portion of an operative communicative connection between the downhole communication sub and the surface communication sub.

26. The telemetry system of claim 25, wherein the measurement tool is also an adapter sub.

27. The telemetry system of claim 25, further comprising a second cable disposed within the drill string and connected across the pair of adapter subs, thereby forming a second communication link connected for communication with the first communication link, the second communication link also providing at least a portion of an operative communicative connection between the downhole communication sub and the surface communication sub.

28. The telemetry system of claim 25, wherein the first communication sub is disposed beneath a kelly joint in the drill string.

29. The telemetry system of claim 25, wherein the first communication sub is disposed above a kelly joint in the drill string.

30. The telemetry system of claim 25, wherein the first communication sub is disposed beneath a power swivel supporting the drill string.
